

CS6202: Problem Set 1

Question 1

Inverse-transform sampling is based on the probability integral transform which states the following—if X is continuous random variable (RV) with the cumulative distribution function (CDF) F_X , then the random variable Y has the uniform distribution on $[0, 1]$. Verify this statement by giving an example in the context of normalizing flows (based on the slides on “Transformation of a Random Variable” from the presentation). Specifically, define a RV X with probability density $p(x)$ and the smooth, invertible transformation function $f = F_X$. Derive the analytic density of $Y = f(X)$ and show that it is equal to $\mathcal{U}(0, 1)$, either using the CDF technique or the general change-of-variable formula.

Solution 1

Let $p(x) = \lambda e^{-\lambda x}$ which is the exponential distribution where $\lambda > 0$ and support $x \in [0, \infty)$. The CDF of the exponential distribution is given by $F_X(x) = 1 - e^{-\lambda x}$. Define $f = F_X$. Now, if $Y = f(X)$, we can see that the support of $p(y)$ is $[0, 1]$ by plugging in the support of $p(x)$ in f , i.e., $f(0) = 1 - e^{-\lambda \cdot 0} = 0$ and $\lim_{x \rightarrow \infty} 1 - e^{-\lambda x} = 1$.

Now, we show that the density function of Y is 1, i.e., it's a uniform continuous distribution on $[0, 1]$.

- Using the CDF technique:

$$\begin{aligned} F_Y(y) &= P(Y \leq y) \\ &= P(1 - e^{-\lambda X} \leq y) \\ &= P(e^{-\lambda X} \geq -y + 1) \\ &= P(-\lambda X \geq \log(1 - y)) \\ &= P\left(X \leq -\frac{\log(1 - y)}{\lambda}\right) \\ &= F_X\left(-\frac{\log(1 - y)}{\lambda}\right) \end{aligned}$$

Now, $p(y) = F'_Y(y)$

$$\begin{aligned} p(y) &= \frac{d}{dy} \{F_Y(y)\} \\ &= \frac{d}{dy} \left\{ F_X\left(-\frac{\log(1 - y)}{\lambda}\right) \right\} \\ &= \frac{d}{dy} \left\{ \int_0^{-\frac{\log(1 - y)}{\lambda}} \lambda e^{-\lambda x} dx \right\} \\ &= \frac{d}{dy} \left\{ \left[\frac{\lambda e^{-\lambda x}}{-\lambda} \right]_0^{-\frac{\log(1 - y)}{\lambda}} \right\} \\ &= \frac{d}{dy} \left\{ \left[-e^{-\lambda \cdot -\frac{\log(1 - y)}{\lambda}} - [-e^{-\lambda \cdot 0}] \right] \right\} \\ &= \frac{d}{dy} \{[y - 1 - [-1]]\} = \frac{d}{dy} \{y\} = 1 \end{aligned}$$

- Using change-of-variable formula:

The change-of-variable formula says that

$$\begin{aligned}
p(y) &= p(x) \left| \frac{df}{dx} \right|^{-1} \\
&= \lambda e^{-\lambda x} \left| \frac{d}{dx} \{1 - e^{-\lambda x}\} \right|^{-1} \\
&= \lambda e^{-\lambda x} |\lambda e^{-\lambda x}|^{-1} \\
&= \frac{\lambda e^{-\lambda x}}{\lambda e^{-\lambda x}} = 1
\end{aligned}$$

Question 2

The transformation $f(\mathbf{z}) = \mathbf{z} + \mathbf{u}h(\mathbf{w}^\top \mathbf{z} + b)$ used in planar flows is not always invertible. What are the constraints on \mathbf{u} , \mathbf{w} , and b (if any) for the invertibility of the function? Derive the constraints for the case when $z, u, w \in \mathbb{R}$ and then extend to the case when $\mathbf{z}, \mathbf{u}, \mathbf{w} \in \mathbb{R}^d$. Assume that the function h is the logistic function $h(x) = \frac{1}{1+e^{-x}}$.

Solution 2

When $z, u, w \in \mathbb{R}$, we have $f(z) = z + u \cdot h(wz + b)$. A sufficient condition for the invertibility of $f(z)$ is that it is an increasing function, i.e., $f'(z) > 0$.

$$\begin{aligned}
f'(z) &> 0 \\
1 + uw \cdot h'(wz + b) &> 0 \\
uw &> -\frac{1}{h'(wz + b)}
\end{aligned}$$

The function $h'(x) = \frac{e^x}{(e^x + 1)^2}$ takes its maximum value at $x = 0$ which is 0.25. Therefore, it is sufficient that $uw > -4$ for the function f to be invertible.

Let's extend this to the case when $\mathbf{z}, \mathbf{u}, \mathbf{w} \in \mathbb{R}^d$. We begin by splitting \mathbf{z} into two components \mathbf{z}_\perp (perpendicular to \mathbf{w}) and \mathbf{z}_\parallel (parallel to \mathbf{w}). Note that \mathbf{z}_\parallel is parallel to \mathbf{w} , it can also be written as $\alpha \frac{\mathbf{w}}{\|\mathbf{w}\|^2}$. With this in mind,

$$f(\mathbf{z}) = \mathbf{z}_\perp + \mathbf{z}_\parallel + \mathbf{u}h(\mathbf{w}^\top \mathbf{z}_\parallel + b) \quad (1)$$

Let $\mathbf{y} = f(\mathbf{z})$; now, \mathbf{z}_\perp can be uniquely computed as follows (given that we have \mathbf{z}_\parallel)

$$\mathbf{z}_\perp = \mathbf{y} - \mathbf{z}_\parallel - \mathbf{u}h(\mathbf{w}^\top \mathbf{z}_\parallel + b) \quad (2)$$

Substituting $\mathbf{z}_\parallel = \alpha \frac{\mathbf{w}}{\|\mathbf{w}\|^2}$ in Eq. (1)

$$f(\mathbf{z}) = \mathbf{z}_\perp + \alpha \frac{\mathbf{w}}{\|\mathbf{w}\|^2} + \mathbf{u}h(\alpha + b) \quad (3)$$

$$\mathbf{w}^\top f(\mathbf{z}) = \alpha + \mathbf{w}^\top \mathbf{u}h(\alpha + b) \quad (\text{dot product with } \mathbf{w}) \quad (4)$$

We need to solve the scalar equation in Eq. (4) to solve for α . For a unique solution, the RHS of Eq. (4) must be an increasing function, i.e.,

$$\begin{aligned}
1 + \mathbf{w}^\top \mathbf{u}h'(\alpha + b) &> 0 \\
\mathbf{w}^\top \mathbf{u} &> -\frac{1}{h'(\alpha + b)}
\end{aligned}$$

Again, as before, $\max h'(x) = 0.25$ at $x = 0$. Therefore, it suffices that $\mathbf{w}^\top \mathbf{u} > -4$.

Question 3

Implement a `Bijector` in Tensorflow Probability for the sigmoid activation function.

$$\sigma(x) = \frac{1}{1 + e^{-x}}$$

Solution 3

Forward function:

$$y = \frac{1}{1 + e^{-x}}$$

Inverse function:

$$x = -\log\left(\frac{1}{y} - 1\right)$$

Inverse Jacobian's diagonal element:

$$\left. \frac{\partial \sigma^{-1}}{\partial y} \right|_{ii} = \frac{1}{y_i - y_i^2}$$

```
1 class Sigmoid(tfb.Bijector):
2     def __init__(self, validate_args=False, name="sigmoid"):
3         super(Sigmoid, self).__init__(
4             forward_min_event_ndims=0,
5             validate_args=validate_args,
6             name=name)
7
8     def _forward(self, x):
9         return 1./(1 + tf.exp(-x))
10
11    def _inverse(self, y):
12        return -tf.log(1/y - 1)
13
14    def _inverse_log_det_jacobian(self, y):
15        I = tf.ones_like(y)
16        J_inv = 1/(y - y ** 2) * I
17        log_abs_det_J_inv = tf.log(tf.abs(J_inv))
18        return log_abs_det_J_inv
```
