### Log-likelihood and Evidence Lower Bound (ELOB)

It is universally true that:

$$\ln(p(X)) = \ln(p(X,Z)) - \ln(p(Z|X))$$

It's also true (a bit silly) that:

$$\ln(p(X)) = [\ln(p(X,Z)) - \ln(q(Z))] - [\ln(p(Z|X)) - \ln(q(Z))]$$

▶ The above is so that we can insert an arbitrary pdf q(Z) into, now we get:

$$\ln(p(X)) = \ln\left(\frac{p(X,Z)}{q(Z)}\right) - \ln\left(\frac{p(Z|X)}{q(Z)}\right)$$

▶ Taking the expectation on both sides, given q(Z):

$$\begin{aligned} & \ln\left(p(X)\right) = \int q(Z) \ln\left(\frac{p(X,Z)}{q(Z)}\right) \mathrm{d}Z - \int q(Z) \ln\left(\frac{p(Z|X)}{q(Z)}\right) \mathrm{d}Z \\ & = \underbrace{\int q(Z) \ln(p(X,Z)) \mathrm{d}Z - \int q(Z) \ln(q(Z)) \mathrm{d}Z}_{\mathcal{L}(q)} + \underbrace{\left(-\int q(Z) \ln\left(\frac{p(Z|X)}{q(Z)}\right) \mathrm{d}Z\right)}_{\mathbb{KL}(q||p)} \\ & = \mathcal{L}(q) + \mathbb{KL}(q||p) \end{aligned}$$

#### Alternative Evidence Lower Bound (ELOB)

We often see the following alternative derivation:

$$\begin{split} \ln\left(\rho(X)\right) &= \log \int_{Z} \rho(X,Z) \mathrm{d}z \\ &= \log \int_{Z} \rho(X,Z) \frac{q(Z)}{q(Z)} \mathrm{d}z \\ &= \log \left(\mathbb{E}_{q} \left[\frac{\rho(X,Z)}{q(Z)}\right]\right) \\ &\geq \mathbb{E}_{q} \left[\log \left(\frac{\rho(X,Z)}{q(Z)}\right)\right] \text{ using Jensen's inequality} \\ &= \mathbb{E}_{q} \left[\log(\rho(X,Z))\right] - \mathbb{E}_{q} \left[\log(q(Z))\right] \\ &\triangleq \mathcal{L}(q) \end{split}$$

It can be proven easily that the "missing" part, i.e.,  $\ln(p(X)) - \mathcal{L}(q) = \mathbb{KL}(q||p)$ .

### Maximize Evidence Lower Bound (ELOB)

$$\ln(p(X)) = \mathcal{L}(q) + \mathbb{KL}(q||p)$$

We can give a name to both terms:

Evidence Lower Bound (ELOB): 
$$\mathcal{L}(q) = \int q(Z) \ln(p(X,Z)) dZ - \int q(Z) \ln(q(Z)) dZ$$

$$\mathbb{KL}(q||p) = \int q(Z) \ln\left(\frac{p(Z|X)}{q(Z)}\right) dZ$$

Notice p(X) is fixed with respect to the choice of q(Z). We wanted to choose a q(Z) function that minimize KL divergence, so that q(Z) becomes closer and closer to p(Z|X). Of course, let's see what happens when q(Z) = p(Z|X):

$$\mathbb{KL}(q||p) = -\int p(Z|X) \ln \left( \frac{p(Z|X)}{p(Z|X)} \right) dZ = 0$$

We know that  $p(X) = \mathcal{L}(q) + \mathbb{KL}(q||p)$ . Minimizing  $\mathbb{KL}(q||p)$  is the same as maximizing the Evidence Lower Bound  $\mathcal{L}(q)$ .

#### Approach One

- Arbitrary (i.e., non Exponential Family ) distributions
- No maximizing variational distribution parameters

## The choice of q(Z)

▶ Suppose let's choose q(Z), such that:

$$q(Z) = \prod_{i=1}^{M} q_i(Z_i)$$

Substitute this choice into Evidence Lower Bound (ELOB):

$$\mathcal{L}(q) = \int q(Z) \ln(p(X, Z)) dZ - \int q(Z) \ln(q(Z)) dZ$$

$$= \underbrace{\int \prod_{i=1}^{M} q_i(Z_i) \ln(p(X, Z)) dZ}_{\text{part (1)}} - \underbrace{\int \prod_{i=1}^{M} q_i(Z_i) \sum_{i=1}^{M} \ln(q_i(Z_i)) dZ}_{\text{part (2)}}$$

## Simplification of (Part 1):

$$\begin{aligned} & (\text{Part 1}) = \int \prod_{i=1}^{M} q_i(Z_i) \ln \left( \rho(X,Z) \right) \mathrm{d}Z \\ & \int \int \int \dots \int \prod_{i=1}^{M} q_i(Z_i) \ln \left( \rho(X,Z) \right) \mathrm{d}Z_1, \mathrm{d}Z_2, \dots, \mathrm{d}Z_M \end{aligned}$$

▶ Rearrange the expression by taking a particular  $q_i(Z_i)$  out of the integral:

$$(\text{Part 1}) = \int_{Z_j} q_j(Z_j) \left( \int_{Z_i \neq j} \cdots \int_{i \neq j} \prod_{i \neq j}^M q_i(Z_i) \ln \left( p(X, Z) \right) \prod_{i \neq j}^M dZ_i \right) dZ_j$$

or, more compactly:

$$(\text{Part 1}) = \int\limits_{Z_j} q_j(Z_j) \left( \int \cdots \int\limits_{Z_{i \neq j}} \ln \left( \rho(X, Z) \right) \prod_{i \neq j}^M q_i(Z_i) dZ_i \right) dZ_j$$

• or, even more meaningfully, it can be put into an expectation function, and since  $\prod_{i\neq j}^{M} q_i(Z_i)$  is a joint probability density

$$(\operatorname{Part} 1) = \int\limits_{Z_j} q_j(Z_j) \left[ \mathbb{E}_{i \neq j} \left[ \ln \left( p(X, Z) \right) \right] \right] dZ_j$$

## Simplification of (Part 2):

(Part 2) = 
$$\int \prod_{i=1}^{M} q_i(Z_i) \sum_{i=1}^{M} \ln (q_i(Z_i)) dZ$$

Note that the above needs to integrate out all  $Z = \{z_1, ..., z_M\}$ , which is quite daunting. However, notice that each term in the sum,  $\sum_{i=1}^M \ln\left(q_i(Z_i)\right)$  involves only a single i, therefore, we are able to simplify the above into the following:

$$(\text{Part 2}) = \sum_{i=1}^{M} \left( \int_{Z_i} q_i(Z_i) \ln (q_i(Z_i)) dZ_i \right)$$

For a particular  $p_j(Z_j)$ , the rest of the sum can be treated like a constant, part 2 can be written as:

$$(\text{Part 2}) = \int\limits_{Z_i} q_i(Z_i) \ln (q_i(Z_i)) dZ_j + \text{const.}$$

where const. are the term does not involve  $Z_i$ .

## Putting Part (1) and Part (2) together:

$$\mathcal{L}(q) = \operatorname{Part}(1) - \operatorname{Part}(2) = \int\limits_{Z_j} q_j(Z_j) \mathbb{E}_{i \neq j} \bigg[ \ln \left( p(X, Z) \right) \bigg] dZ_j - \int\limits_{Z_j} q_j(Z_j) \ln \left( q_j(Z_j) \right) dZ_j + \operatorname{const.}$$

Note that  $\mathbb{E}_{i\neq j}$  [ln (p(X,Z))] would be some ln[ $p(Z_i)$ ], we name it ln $(\tilde{p}_i(X,Z_i))$ , i.e.,:

$$\ln(\tilde{p}_i(X, Z_i)) = \mathbb{E}_{i \neq j} \left[ \ln \left( p(X, Z) \right) \right]$$

Or equivalently we can express Evidence Lower Bound (ELOB) in terms of:

$$\mathcal{L}(q_j) = \int\limits_{Z_j} q_j(Z_j) \ln \left[ rac{ ilde{
ho}_j(X,Z_j)}{q_j(Z_j)} 
ight] + ext{const.}.$$

This is the same as  $-\mathbb{KL}\left(\mathbb{E}_{i\neq j}\left[\ln\left(p(X,Z)\right)\right]\|q_i(Z_i)\right)$ 

▶ This is the key: We can maximize ELOB, or  $\mathcal{L}(q)$ , by minimizing this special KL divergence, where we can find approximate and optimal  $q_i^*(Z_i)$ , such that:

$$\ln\left(q_{i}^{*}(Z_{i})\right) = \mathbb{E}_{i\neq j}\left[\ln\left(p(X,Z)\right)\right]$$

## Example: Gaussian-Gamma Conjugate prior

▶ Let  $\mathcal{D} = \{x_1, \dots x_n\}$ :

$$p(\mathcal{D}|\mu,\tau) = \prod_{i=1}^{n} \left(\frac{\tau}{2\pi}\right)^{\frac{1}{2}} \exp\left(\frac{-\tau}{2}(x_i - \mu)^2\right)$$

$$= \left(\frac{\tau}{2\pi}\right)^{\frac{n}{2}} \exp\left(\frac{-\tau}{2}\sum_{i=1}^{n}(x_i - \mu)^2\right)$$

$$= p(\mu|\tau) = \mathcal{N}(\mu_0, (\lambda_0\tau)^{-1}) \propto \exp\left(\frac{-\lambda_0\tau}{2}(\mu - \mu_0)^2\right)$$

$$p(\tau) = \text{Gamma}(\tau|a_0, b_0) \propto \tau^{a_0 - 1} \exp^{-b_0\tau}$$

Complete data-likelihood is:

$$p(\mathcal{D}, \mu, \tau) = p(\mathcal{D}|\mu, \tau)p(\mu|\tau)p(\tau)$$

### Of course, due to conjugacy, the solution can be found exactly:

$$p(\mu, \tau | \mathbf{d}) \propto p(\mathcal{D} | \mu, \tau) p(\mu | \tau) p(\tau) = \mathcal{N}(\mu_n, (\lambda_n \tau)^{-1}) \text{Gamma}(\tau | a_n, b_n)$$
where:

$$\mu_{n} = \frac{\lambda_{0}\mu_{0} + n\bar{x}}{\lambda_{0} + n}$$

$$\lambda_{n} = \lambda_{0} + n$$

$$a_{n} = a_{0} + n/2$$

$$b_{n} = b_{0} + \frac{1}{2} \sum_{i=1}^{n} (x_{i} - \bar{x})^{2} + \frac{\lambda_{0}n(\bar{x} - \mu_{0})^{2}}{2(\lambda_{0} + n)}$$

However, for demo purpose, we assume  $q(\mu, \tau)$ :

$$q(\mu, \tau) = q_{\mu}(\mu)q_{\tau}(\tau)$$

# Computing $\ln\left(q_{\mu}^{*}(\mu)\right) = \mathbb{E}_{q_{\tau}(\tau)}\left[\ln\left(p(\mu, \tau | \mathcal{D})\right)\right]$ (1)

$$\begin{split} &\ln\left(q_{\mu}^{*}(\mu)\right) = \mathbb{E}_{q_{\tau}}\left[\ln\left(p(\mu,\tau|\mathcal{D})\right)\right] \\ &= \mathbb{E}_{q_{\tau}}\left[\ln(p(\mathcal{D}|\mu,\tau)) + \ln p(\mu|\tau)\right] + \text{const.} \qquad \text{remove terms do NOT contain } \mu \\ &= \mathbb{E}_{q_{\tau}}\left[\underbrace{-\frac{\tau}{2}\sum_{i=1}^{n}(x_{i}-\mu)^{2}}_{\ln(p(\mathcal{D}|\mu,\tau))} + \underbrace{\frac{\lambda_{0}\tau}{2}(\mu-\mu_{0})^{2}}_{\ln p(\mu|\gamma)}\right] + \text{const.} \\ &= -\frac{\mathbb{E}_{q_{\tau}}\left[\tau\right]}{2}\left[\underbrace{\sum_{i=1}^{n}(x_{i}-\mu)^{2} + \lambda_{0}(\mu-\mu_{0})^{2}}_{\text{terms contain } \mu \text{ but does not contain } \tau}\right] + \text{const.} \end{split}$$

Completing the square for the  $\mu$  terms:

$$\sum_{i=1}^{n} (x_i - \mu)^2 + \lambda_0 (\mu - \mu_0)^2 = n\mu^2 - 2n\mu\bar{x} + \lambda_0\mu^2 - 2\lambda_0\mu_0\mu + \text{const.}$$

$$= (n + \lambda_0)\mu^2 - 2\mu(n\bar{x} + \lambda_0\mu_0) = (n + \lambda_0)\left(\mu^2 - \frac{2\mu(n\bar{x} + \lambda_0\mu_0)}{(n + \lambda_0)}\right)$$

$$= (n + \lambda_0)\left(\mu - \frac{(n\bar{x} + \lambda_0\mu_0)}{(n + \lambda_0)}\right)^2 + \text{const.}$$

# Computing $\ln\left(q_{\mu}^{*}(\mu)\right)=\mathbb{E}_{q_{\tau}(\tau)}\left[\ln\left(p(\mu,\tau|\mathcal{D})\right)\right]$ (2)

Therefore, we have:

$$\begin{aligned} \ln\left(q_{\mu}^{*}(\mu)\right) &= -\frac{\mathbb{E}_{q_{\tau}}[\tau]}{2} \left[\sum_{i=1}^{n} (x_{i} - \mu)^{2} + \lambda_{0}(\mu - \mu_{0})^{2}\right] + \text{const.} \\ &= -\frac{\mathbb{E}_{q_{\tau}}[\tau](n + \lambda_{0})}{2} \left(\mu - \frac{(n\bar{x} + \lambda_{0}\mu_{0})}{(n + \lambda_{0})}\right)^{2} + \text{const.} \\ &= \mathcal{N}\left(\frac{n\bar{x} + \lambda_{0}\mu_{0}}{n + \lambda_{0}}, \mathbb{E}_{q_{\tau}}[\tau](n + \lambda_{0})\right) \end{aligned}$$

# Computing $\ln\left(q_i^*(\tau)\right) = \mathbb{E}_{q_\mu(\mu)}\left[\ln\left(p(\mu,\tau|\mathcal{D})\right)\right]$ (1)

$$\begin{split} &\ln\left(q_{\tau}^{*}(\tau)\right) = \mathbb{E}_{q_{\mu}}\left[\ln\left(p(\mu,\tau|\mathcal{D})\right)\right] \\ &= \mathbb{E}_{q_{\mu}}\left[\ln(p(\mathcal{D}|\mu,\tau)) + \ln p(\mu|\tau) + \ln p(\tau)\right] + \text{const.} \\ &= \mathbb{E}_{q_{\mu}}\left[\underbrace{\frac{n}{2}\ln\left(\tau\right) - \frac{\tau}{2}\sum_{i=1}^{n}(x_{i}-\mu)^{2}}_{\ln(p(\mathcal{D}|\mu,\tau))} \underbrace{-\frac{\lambda_{0}\tau}{2}(\mu-\mu_{0})^{2}}_{\ln p(\mu|\gamma)} \underbrace{+(a_{0}-1)\ln(\tau) - b_{0}\tau}_{\ln p(\tau)}\right] + \text{const.} \end{split}$$

Bring terms without  $\mu$  outside of the integral:

$$\begin{split} &=\frac{n}{2}\ln(\tau)+(a_0-1)\ln(\tau)-b_0\tau-\frac{\tau}{2}\mathbb{E}_{q_{\mu}(\mu)}\left[\sum_{i=1}^n(x_i-\mu)^2+\lambda_0(\mu-\mu_0)^2\right]+\text{const.} \\ &=\left(\underbrace{\frac{n}{2}+a_0-1}_{a_n}-1\right)\ln(\tau)-\tau\left(\underbrace{b_0+\frac{1}{2}\mathbb{E}_{q_{\mu}(\mu)}\left[\sum_{i=1}^n(x_i-\mu)^2+\lambda_0(\mu-\mu_0)^2\right]}_{b_n}\right)+\text{const.} \end{split}$$

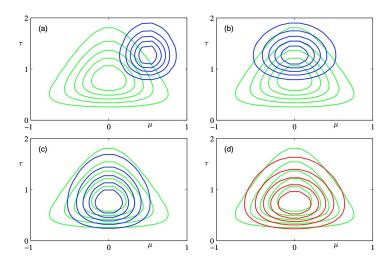

# Computing $\ln\left(q_i^*(\tau)\right) = \mathbb{E}_{q_\mu(\mu)}\left[\ln\left(p(\mu,\tau|\mathcal{D})\right)\right]$ (2)

We can rewrite.

$$\begin{split} b_n &= b_0 + \frac{1}{2} \mathbb{E}_{q_{\mu}} \left[ \sum_{i=1}^n (x_i - \mu)^2 + \lambda_0 (\mu - \mu_0)^2 \right] \\ &= b_0 + \frac{1}{2} \mathbb{E}_{q_{\mu}} \left[ -2\mu n \bar{x} + n\mu^2 + \lambda_0 \mu^2 - 2\lambda_0 \mu_0 \mu \right] + \sum_{i=1}^n (x_i)^2 + \lambda_0 \mu_0^2 \\ &= b_0 + \frac{1}{2} \left[ (n + \lambda_0) \mathbb{E}_{q_{\mu}} [\mu^2] - 2 (n \bar{x} + \lambda_0 \mu_0) \mathbb{E}_{q_{\mu}} [\mu] + \sum_{i=1}^n (x_i)^2 + \lambda_0 \mu_0^2 \right] \end{split}$$

We will compute  $\mathbb{E}_{q_{\mu}}[\mu]$  and  $\mathbb{E}_{q_{\mu}}[\mu^2]$  since we know of  $q_{\mu}(\mu)$  from previously.

## Figure and Demo

Also see Matlab Demo!

#### Approach Two

ightharpoonup Perform direct maximisation over q(Z) using variational calculus

## Functional identity

$$G(f_X(x), f_Y(y)) = \int_X \int_Y f_X(x) f_Y(y) \ln p(x, y) dx dy \implies$$

$$\frac{\delta G(f_X(x), f_Y(y))}{\delta f_X(x')} = \int_X \int_Y \frac{\delta f_X(x)}{\delta f_X(x')} f_Y(y) \ln p(x, y) dx dy$$

$$= \int_X \int_Y \delta(x - x') f_Y(y) \ln p(x, y) dx dy$$

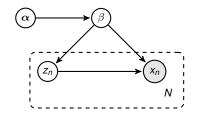

$$= \int_Y f_Y(y) \ln p(x', y) dy$$

Let  $Z \triangleq (z, \theta)$   $p(X, Z, \theta) = p(X, Z|\theta)p(\theta)$   $q(Z, \theta) = q_Z(Z)q_\theta(\theta)$ : Evidence Lower Bound (ELBO) can be written as:

#### Approach Three

- Exponential Family distributions
- Maximizing variational distribution parameters
- Introduction to Stochastic Variational Inference (SVI)

#### Problem to consider:

$$p(X, Z, \beta | \alpha) = p(\beta | \alpha) \prod_{n=1}^{N} p(x_n, z_n | \beta)$$
$$p(x_n, z_n | x_{-n}, z_{-n}, \beta, \alpha) = p(x_n, z_n | \beta, \alpha)$$

All posterior is based on Exponential family:

$$p(\beta|X,Z,\alpha) = h(\beta) \exp\left\{\eta_g(X,Z,\alpha)^T t(\beta) - A_g(\eta_g(X,Z,\alpha))\right\}$$

$$p(z_{n,j}|x_n,z_{n,-j},\beta) = h(z_{n,j}) \exp\left\{\eta_l(x_n,z_{n,-j},\beta)^T t(z_{n,j}) - A_l(\eta_l(x_n,z_{n,-j},\beta))\right\}$$

### Let's look at some Important Distributions: Exponential Family

Most of the distributions we are going to look at are from **exponential family exponential family** can be expressed in terms of its natural parameters:

$$h(x) \exp \left(T(x)^T \eta - A(\eta)\right)$$

Think about why is this representation useful?

**Always have in mind** ask yourself where are the **support** of these distributions, i.e., where p(X) > 0?

## More about Gaussian 1-d: Natural Parameter Representation

$$\mathcal{N}(x; \mu, \sigma^2) = (2\pi\sigma^2)^{-1/2} \exp^{-\frac{(x-\mu)^2}{2\sigma^2}}$$

$$= \exp\left(-\frac{x^2 - 2x\mu + \mu^2}{2\sigma^2} - \frac{1}{2}\ln(2\pi\sigma^2)\right)$$

$$= \exp\left(-\frac{1}{2\sigma^2}x^2 + \frac{\mu}{\sigma^2}x - \frac{\mu^2}{2\sigma^2} - \frac{1}{2}\ln(2\pi\sigma^2)\right)$$

$$= \exp\left(\underbrace{\begin{bmatrix} x \\ x^2 \end{bmatrix}^T}_{T(X)} \left[ \frac{\mu}{\frac{\sigma^2}{2\sigma^2}} \right] - \frac{\mu^2}{2\sigma^2} - \frac{1}{2}\ln(2\pi\sigma^2)\right)$$

## More about Gaussian 1-d: Natural Parameter Representation (2)

► Reverse is:  $\theta = \begin{bmatrix} \mu \\ \sigma^2 \end{bmatrix} = \begin{bmatrix} \frac{-\eta_1}{2\eta_2} \\ \frac{-1}{2\eta_2} \end{bmatrix}$ 

$$\begin{split} \tilde{\mathcal{N}}(x,\eta) &= \exp\left(\left[\frac{x}{x^2}\right]^T \begin{bmatrix} \eta_1 \\ \eta_2 \end{bmatrix} - \frac{\mu^2}{2\sigma^2} - \frac{1}{2}\ln(2\pi\sigma^2)\right) \\ &= \exp\left(\left[\frac{x}{x^2}\right]^T \begin{bmatrix} \eta_1 \\ \eta_2 \end{bmatrix} - \frac{\left(\frac{-\eta_1}{2\eta_2}\right)^2}{2\left(\frac{-1}{2\eta_2}\right)} - \frac{1}{2}\ln\left(2\pi\left(\frac{-1}{2\eta_2}\right)\right)\right) \\ &= \exp\left(T(x)^T \eta + \frac{\eta_1^2}{4\eta_2} - \frac{1}{2}\ln\left(\frac{2\pi}{-2\eta_2}\right)\right) \\ &= \exp\left(T(x)^T \eta + \frac{\eta_1^2}{4\eta_2} + \frac{1}{2}\ln(-2\eta_2) - \frac{1}{2}\ln(2\pi)\right) \end{split}$$

$$\mathcal{N}_{\mathsf{nat}}(x,\eta) = \exp\left(T(x)^{T}\eta - \underbrace{\left(rac{-\eta_{1}^{2}}{4\eta_{2}} - rac{1}{2}\ln(-2\eta_{2})
ight)}_{A(\eta)} - rac{1}{2}\ln(2\pi)
ight)$$

## conditional per $(x_n, z_n)$ : $p(\beta|x_n, z_n)$

Prior:

$$p(\beta) = h(\beta) \exp\{\alpha^T t(\beta) - A_g(\alpha)\} = \underbrace{\exp(-A_g(\alpha))}_{\text{normalization}} h(\beta) \exp\{\alpha^T t(\beta)\}$$

$$\implies \int_{\beta} h(\beta) \exp\{\alpha^T t(\beta)\} = \exp(A_g(\alpha))$$

Let sufficient statistics  $t(\beta) = [\beta, \underbrace{-A_l(\beta)}^T]^T \implies \alpha = [\alpha_1 \ \alpha_2]^T$ :

$$p(\beta) = h(\beta) \exp \left\{ \left[ \alpha_1, \alpha_2 \right]^T \left[ \beta, \underbrace{-A_l(\beta)}_{\text{same}} \right] - A_g(\alpha) \right\}$$

Likelihood density per (x<sub>n</sub>, z<sub>n</sub>) is:

$$p(x_n, z_n | \beta) = h(x_n, z_n) \exp \left\{ t(x_n, z_n) \beta \underbrace{-A_l(\beta)}_{\text{same}} \right\}$$

Posterior is:

$$\rho(\beta|x_n, z_n, \alpha) \propto \underbrace{h(\beta) \exp\{\alpha^T t(\beta)\}}_{} \underbrace{\exp\{t(x_n, z_n)\beta - A_l(\beta)\}}_{}$$

$$= h(\beta) \exp\{(\alpha_1 + t(x_n, z_n))\beta - \alpha_2 A_l(\beta) - A_l(\beta)\}$$

$$= h(\beta) \exp\{(\alpha_1 + t(x_n, z_n))\beta - (\alpha_2 + 1)A_l(\beta)\}$$

$$= h(\beta) \exp\{[\alpha_1 + t(x_n, z_n) - \alpha_2 + 1]^T t(\beta)\}$$

### The complete posterior

Complete likelihood:

$$p(X, Z|\beta) = \prod_{n=1}^{N} h(x_n, z_n) \exp\{\beta^T t(x_n, z_n) - A_I(\beta)\} = h(X, Z) \exp\left\{\sum_{n=1}^{N} \beta^T t(x_n, z_n) - N \times A_I(\beta)\right\}$$

Complete posterior:

Since: 
$$p(\beta|x_n, z_n, \alpha) \propto h(\beta) \exp\{[\alpha_1 + t(x_n, z_n) \quad \alpha_2 + 1]^T t(\beta)\}$$
:

$$\implies p(\beta|X,Z,\alpha) \propto h(\beta) \exp \left\{ \left[ \alpha_1 + \sum_{n=1}^N t(x_n,z_n) \quad \alpha_2 + N \right]^T t(\beta) \right\}$$

When we use the expression:

$$p(\beta|X,Z,\alpha) = h(\beta) \exp\{\eta_g(X,Z,\alpha)^T t(\beta) - A_g(\eta_g(X,Z,\alpha))\}$$

$$\implies \eta_g(X,Z,\alpha) = \left[\alpha_1 + \sum_{n=1}^N t(x_n,z_n) \quad \alpha_2 + N\right]$$

$$\implies A_g(\eta_g(X,Z,\alpha)) = \int_{\beta} h(\beta) \exp\{\eta_g(X,Z,\alpha)^T t(\beta)\}$$

## Example: Posterior of Gaussian mean (1)

To summarise:

$$p(\beta|X,Z,\alpha) \propto h(\beta) \exp\left\{ \left[ \hat{\alpha_1} \quad \hat{\alpha_2} \right]^T \left[ \beta \quad -A_l(\beta) \right] \right\}$$

$$= h(\beta) \exp\left\{ \left[ \underbrace{\alpha_1 + \sum_{n=1}^{N} t(x_n, z_n)}_{\hat{\alpha_1}} \quad \underbrace{\alpha_2 + N}_{\hat{\alpha_2}} \right]^T t(\beta) \right\}$$

Example: suppose data x<sub>i</sub> come from unit variance Gaussian:

$$p(x|\mu) = \frac{1}{\sqrt{2\pi}} \exp\left\{-\frac{1}{2}(x-\mu)^2\right\} = \underbrace{\frac{\exp\left(-x^2/2\right)}{\sqrt{2\pi}}}_{h(x)} \exp\left\{\underbrace{\frac{\mu}{\beta}\underbrace{x}_{l(x)} - \underbrace{\frac{\mu^2}{2}}_{A_l(\beta)}\right\}}_{2}$$

So we have:

$$eta = \mu$$
  $t(x) = x$   $A_l(eta) = rac{eta^2}{2}$   $h(x) = rac{\exp\left(-x^2/2\right)}{\sqrt{2\pi}}$ 

## Example: Posterior of Gaussian mean (2)

$$p(x|\mu) = \frac{\exp\left(-x^2/2\right)}{\sqrt{2\pi}} \exp\left\{\mu x - \frac{\mu^2}{2}\right\} = \frac{\exp\left(-x^2/2\right)}{\sqrt{2\pi}} \exp\left\{\beta x + \underbrace{-\frac{\beta^2}{2}}_{A_l(\beta)}\right\}$$

For the above likelihood, its conjugate prior MUST be in the form of:

$$\begin{split} p(\beta|\alpha) &= h(\beta) \exp \left\{ \alpha_1 \beta + \alpha_2 \underbrace{\left(-\beta^2/2\right)}_{A_f(\beta)} - A_g(\alpha) \right\} \\ &= h(\beta) \exp \left\{ \begin{bmatrix} \alpha_1 & -\frac{\alpha_2}{2} \end{bmatrix}^T \begin{bmatrix} \beta & \beta^2 \end{bmatrix} - A_g(\alpha) \right\} \end{split}$$

## Example: Posterior of Gaussian mean (3)

Since we know,

$$p(eta|lpha) = h(eta) \exp \left\{ [lpha_1 \quad lpha_2/2]^T \left[eta \quad eta^2 
ight] - A_g(lpha) 
ight\}$$

From our knowledge, a distribution with  $t(\beta) = [\beta \quad \beta^2]$  is a Gaussian.

- Suppose the data come from an exponential family. Every exponential family has a conjugate prior in theory.
- ▶ The natural parameter  $\alpha = [\alpha_1, \alpha_2]$  has dimension dim( $\beta$ ) + 1.
- ▶ The sufficient statistics of the prior are  $[\beta, -A_l(\beta)]$

# For exponential family distribution: $\mathbb{E}_q[t(\beta)] = \nabla_{\lambda} A_g(\lambda)$

Given 
$$q(\beta|\lambda) = h(\beta) \exp\{\lambda^T t(\beta) - A_g(\lambda)\} = \frac{1}{\exp(A_g(\lambda))} h(\beta) \exp\{\lambda^T t(\beta)\}$$
  
Why  $\mathbb{E}_q[t(\beta)] = \nabla_\lambda A_g(\lambda)$   
 $\beta|\lambda) d\beta = \int h(\beta) \exp\{\lambda^T t(\beta) - A_g(\lambda)\} d\beta = 0$ 

$$\begin{split} &\int_{\beta} \mathsf{q}(\beta|\lambda) \mathsf{d}\beta = \int_{\beta} h(\beta) \exp\{\lambda^T t(\beta) - A_g(\lambda)\} \mathsf{d}\beta = 0 \\ &\implies \nabla_{\lambda} \left( \int_{\beta} h(\beta) \exp\{\lambda^T t(\beta) - A_g(\lambda)\} \mathsf{d}\beta \right) = 0 \\ &\implies \int_{\beta} \nabla_{\lambda} \left( h(\beta) \exp\{\lambda^T t(\beta) - A_g(\lambda)\} \right) \mathsf{d}\beta = 0 \\ &\implies \int_{\beta} \left( h(\beta) \exp\{\lambda^T t(\beta) - A_g(\lambda)\} \right) (t(\beta) - \nabla_{\lambda} A_g(\lambda)) = 0 \\ &\implies \int_{\beta} \left( h(\beta) \exp\{\lambda^T t(\beta) - A_g(\lambda)\} \right) t(\beta) - \int_{\beta} \left( h(\beta) \exp\{\lambda^T t(\beta) - A_g(\lambda)\} \right) \nabla_{\lambda} A_g(\lambda) = 0 \\ &\implies \mathbb{E}_{g}[t(\beta)] - \nabla_{\lambda} A_g(\lambda) = 0 \end{split}$$

## The choice of $q(\beta, Z)$

We choose  $q(\beta, Z)$  to decouple  $\beta$  and Z completely:

$$q(\beta, Z) = q(\beta|\lambda) \prod_{n=1}^{N} \prod_{j=1}^{J} q(z_{n,j}|\phi_{n,j})$$

•  $q(\beta|\lambda)$  is the SAME distribution type as  $p(\beta|X,Z,\alpha)$ , they only differ in parameter

$$\begin{split} q(\beta|\lambda) &= h(\beta) \exp\{\lambda^T t(\beta) - A_g(\lambda)\} \\ \text{compare with:} \qquad p(\beta|X,Z,\alpha) &= h(\beta) \exp\left\{\eta_g(X,Z,\alpha)^T t(\beta) - A_g(\eta_g(X,Z,\alpha))\right\} \end{split}$$

•  $q(z_{n,j}|\phi_{n,j})$  is the SAME distribution type as  $p(z_{n,j}|x_n,z_{n,-j},\beta)$ , they only differ in parameter

$$\begin{aligned} q(z_{n,j}|\phi_{n,j}) &= h(z_{n,j}) \exp\left\{\phi_{n,j}^\intercal t(z_{n,j}) - A_l(\phi_{n,j})\right\} \\ \text{compare with:} \quad & \rho(z_{n,j}|x_n,z_{n,-j},\beta) = h(z_{n,j}) \exp\left\{\eta_l(x_n,z_{n,-j},\beta)^\intercal t(z_{n,j}) - A_l(\eta_l(x_n,z_{n,-j},\beta))\right\} \end{aligned}$$

### Update for $\mathcal{L}(\lambda)$

We need to maximize the ELBO, i.e.,

$$\mathcal{L}(q) \triangleq \mathbb{E}_q[\log p(X, Z, \beta | \alpha)] - \mathbb{E}_q[\log q(Z, \beta)]$$

Note that q used here is  $q(\beta, Z)$  not just  $q(\beta|\lambda)$ 

$$\begin{split} \mathcal{L}(\lambda) &= \mathbb{E}_{q}[\log p(\beta|X,Z,\alpha)] + \mathbb{E}_{q}[\log p(X,Z)] - \mathbb{E}_{q}[\log q(\beta)] \\ &= \mathbb{E}_{q}[\log p(\beta|X,Z,\alpha)] - \mathbb{E}_{q}[\log q(\beta)] + \text{const.} \\ &= \mathbb{E}_{q}\left[\log\left(h(\beta)\exp\{\eta_{g}(x,z,\alpha)^{T}t(\beta) - A_{g}(\eta_{g}(x,z,\alpha))\}\right)\right] - \mathbb{E}_{q}[\log q(\beta)] + \text{const.} \\ &= \mathbb{E}_{q}[\log(h(\beta))] + \underbrace{\mathbb{E}_{q}[\eta_{g}(x,z,\alpha)^{T}t(\beta)]}_{=q} - \mathbb{E}_{q}[\log h(\beta)\exp\{\lambda^{T}t(\beta) - A_{g}(\lambda)\}] + \text{const.} \\ &= \mathbb{E}_{q}[\log(h(\beta))] + \underbrace{\mathbb{E}_{q(Z|\Phi)}[\eta_{g}(x,z,\alpha)]^{T}\mathbb{E}_{q(\beta|\lambda)}[t(\beta)]}_{=q} - \mathbb{E}_{q}[\log h(\beta)] - \mathbb{E}_{q}[\lambda^{T}t(\beta)] + A_{g}(\lambda) + \text{const.} \\ &= \mathbb{E}_{q(Z|\Phi)}[\eta_{g}(x,z,\alpha)]^{T}\mathbb{E}_{q}[t(\beta)] - \lambda^{T}\mathbb{E}_{q}[t(\beta)] + A_{g}(\lambda) + \text{const.} \end{split}$$

Substitute  $\mathbb{E}_q[t(\beta)] = \nabla_{\lambda} A_g(\lambda)$ :

$$\mathcal{L}(\lambda) = \mathbb{E}_{q(Z|\Phi)}[\eta_g(x,z,\alpha)]^T \nabla_{\lambda} A_g(\lambda) - \lambda^T \nabla_{\lambda} A_g(\lambda) + A_g(\lambda) + \text{const.}$$

## Update for $\mathcal{L}(\lambda)$

$$\mathcal{L}(\lambda) = \mathbb{E}_{q(Z|\Phi)}[\eta_g(x, z, \alpha)]^T \nabla_{\lambda} A_g(\lambda) - \lambda^T \nabla_{\lambda} A_g(\lambda) + A_g(\lambda) + \text{const.}$$

Maximize  $\mathcal{L}(\lambda)$  we get:

$$\nabla_{\lambda} \mathcal{L}(\lambda) = \mathbb{E}_{q(Z|\Phi)} [\eta_{g}(x, z, \alpha)]^{T} \nabla_{\lambda}^{2} A_{g}(\lambda) \underbrace{-\nabla_{\lambda} A_{g}(\lambda) - \lambda^{T} \nabla_{\lambda}^{2} A_{g}(\lambda)}_{-} + \nabla_{\lambda} A_{g}(\lambda) = 0$$

$$= \mathbb{E}_{q(Z|\Phi)} [\eta_{g}(x, z, \alpha)]^{T} \nabla_{\lambda}^{2} A_{g}(\lambda) - \lambda^{T} \nabla_{\lambda}^{2} A_{g}(\lambda) = 0$$

$$\implies \nabla_{\lambda}^{2} A_{g}(\lambda) \left( \mathbb{E}_{q(Z|\Phi)} [\eta_{g}(x, z, \alpha)]^{T} - \lambda^{T} \right) = 0$$

$$\lambda = \mathbb{E}_{q(Z|\Phi)}[\eta_g(x, z, \alpha)]$$

## Update for $\mathcal{L}(\phi_{n,j})$

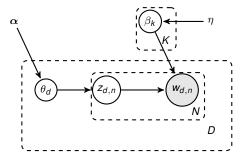

In a very similar fashion to  $\mathcal{L}(\lambda)$ , we can prove:

$$\nabla_{\phi_{n,j}}\mathcal{L}(\phi_{n,j}) = \nabla^2_{\phi_{n,j}}A_I(\phi_{n,j}) \left(\mathbb{E}_{q(\lambda)}[\eta_I(x_n,z_{n,-j},\beta)]^T - \phi_{n,j}^T\right) = 0$$

$$\phi_{n,j} = \mathbb{E}_{q(\lambda)}[\eta_l(x_n, z_{n,-j}, \beta)]$$

Continue next time for Stochastic Maximization ...

#### **Latent Dirichlet Allocation**

- ▶  $\beta_k \sim \text{Dir}(\eta, ..., \eta)$  for  $k \in \{1, ..., K\}$ .
- For each document d:  $\theta \sim \operatorname{Dir}(\alpha, \dots, \alpha)$ For each word  $w \in \{1, \dots, N\}$ :  $z_{dn} \sim \operatorname{Mult}(\theta_d)$   $w_{dn} \sim \operatorname{Mult}(\beta_{Z_{dn}})$

## Updating $q(z_{d,n}|\phi_{d,n})$ : posterior conditional in Exponential Family form

$$\begin{split} p(z_{dn} = k | \theta_d, \beta_{1:K}, w_{d,n}) &\propto p(z_{d,n} = k | \theta_d) p(w_{d,n} | z_{d,n} = k, \beta_{1:K}) \\ &= \mathsf{Mult}(\theta_{d,k}) \times \mathsf{Mult}(\beta_{k,w_{d,n}}) \\ &\propto \mathsf{exp}\left(\underbrace{\mathsf{log}(\theta_{d,k}) + \mathsf{log}(\beta_{k,w_{d,n}})}_{\eta_l(\theta_d, \beta_{1:K}, w_{d,n})} \times \underbrace{1}_{t(z_{d,n})}\right) \end{split}$$

## Updating $q(z_{d,n}|\phi_{d,n})$ : optimize $\phi_{d,n}$

- Fact about Dirichlet Distribution  $\theta \sim \text{Dir}(\gamma_1, \dots \gamma_K) \implies \mathbb{E}[\log(\theta_k)|\gamma] = \Psi(\gamma_k) \Psi\left(\sum_{i=1}^K \gamma_i\right)$
- In terms of natural parameter:

$$\begin{split} \eta\left(\phi_{d,n}^{k}\right) &= \log\left(\phi_{d,n}^{k}\right) \propto \mathbb{E}_{q(\theta_{d})q(\beta_{k})}\left[\eta_{l}\left(\theta_{d},\beta_{1:K}, \textit{W}_{d,n}\right)\right] \\ &= \mathbb{E}_{q(\theta_{d})}\left[\log(\theta_{d,k})\right] + \mathbb{E}_{q(\beta_{k})}\left[\log(\beta_{k,\textit{W}_{d,n}})\right] \\ &= \Psi(\gamma_{d,k}) - \Psi\left(\sum_{k=1}^{K}\gamma_{d,k}\right) + \Psi\left(\lambda_{k,\textit{W}_{d,n}}\right) - \Psi\left(\sum_{v}\lambda_{k,v}\right) \end{split}$$

Change it back to traditional parameter:

$$\implies \phi_{d,n}^k \propto \exp \left[ \Psi(\gamma_{d,k}) - \underbrace{\Psi\left(\sum_{k=1}^K \gamma_{d,k}\right)}_{\text{irrelevant in proportionality}} + \Psi\left(\lambda_{k,w_{d,n}}\right) - \Psi\left(\sum_{\nu} \lambda_{k,\nu}\right) \right]$$

$$\propto \exp \left[ \Psi(\gamma_{d,k}) + \Psi\left(\lambda_{k,w_{d,n}}\right) - \Psi\left(\sum_{\nu} \lambda_{k,\nu}\right) \right]$$

## Updating $q(\theta_d|\gamma_d)$ : posterior conditional in Exponential Family form

$$\begin{split} & p(\theta_{d}|\mathcal{Z}_{d}) = p(\theta_{d}|\alpha) \prod_{n=1}^{N} p(\mathcal{Z}_{d,n}|\theta_{d}) = \mathsf{Dir}(\alpha) \times \prod_{n=1}^{N} \mathsf{Mult}(\mathcal{Z}_{d,n}|\theta_{d}) \\ & = \prod_{k} \left( \theta_{d,k}^{\alpha_{k}-1} \prod_{n=1}^{N} \theta_{d,k}^{\delta(\mathcal{Z}_{d,n},k)} \right) \\ & = \exp \left[ \log \left( \prod_{k} \left( \theta_{d,k}^{\alpha_{k}-1} \prod_{n=1}^{N} \theta_{d,k}^{\delta(\mathcal{Z}_{d,n},k)} \right) \right) \right] \\ & = \exp \left[ \sum_{k} \log \left( \theta_{d,k}^{\alpha_{k}-1} \prod_{n=1}^{N} \theta_{d,k}^{\delta(\mathcal{Z}_{d,n},k)} \right) \right] = \exp \left[ \sum_{k} \left( \log \theta_{d,k}^{\alpha_{k}-1} + \sum_{n=1}^{N} \log \left( \theta_{d,k}^{\delta(\mathcal{Z}_{d,n},k)} \right) \right) \right] \\ & = \exp \left[ \sum_{k} \left( (\alpha_{k}-1) \log \theta_{d,k} + \sum_{n=1}^{N} \delta(\mathcal{Z}_{d,n},k) \log \theta_{d,k} \right) \right] \\ & = \exp \left[ \sum_{k} \left( \alpha_{k} - 1 + \sum_{n=1}^{N} \delta(\mathcal{Z}_{d,n},k) \right) \log \left( \theta_{d,k} \right) \right] \\ & = \exp \left[ \sum_{k} \left( (\alpha_{1}-1+n_{1}) \dots (\alpha_{K}-1+n_{K}) \right)^{T} \underbrace{\left[ \log(\theta_{d,1}) \dots \log(\theta_{d,K}) \right]}_{I(\theta_{d})} \right] \right) \text{ by letting } n_{k} = \sum_{n=1}^{N} \delta(\mathcal{Z}_{d,n},k) \end{aligned}$$

# Updating $q(\theta_d|\gamma_d)$ : optimize $\gamma_d$

- In terms of natural parameter:

$$\begin{split} \eta(\gamma_{d}) &= \mathbb{E}_{q(z_{d,n}|\phi_{d,n})} \left[ \eta_{I} \left( \alpha, z_{d} \right) \right] \\ &= \mathbb{E}_{q(z_{d,n}|\phi_{d,n})} \left[ \left[ \left( \alpha_{1} - 1 + n_{1} \right) \dots \left( \alpha_{K} - 1 + n_{K} \right) \right] \right] \\ &= \left[ \left( \alpha_{1} - 1 + \sum_{n=1}^{N} \delta(z_{d,n}, 1) \phi_{d,n}^{1} \right) \dots \left( \alpha_{K} - 1 + \sum_{n=1}^{N} \delta(z_{d,n}, K) \phi_{d,n}^{K} \right) \right] \end{split}$$

Change it back to traditional parameter:

$$\gamma_{d} = \left[ \left( \alpha_{1} + \sum_{n=1}^{N} \delta(Z_{d,n}, 1) \phi_{d,n}^{1} \right) \dots \left( \alpha_{K} + \sum_{n=1}^{N} \delta(Z_{d,n}, K) \phi_{d,n}^{K} \right) \right]$$
$$= \alpha + \sum_{n=1}^{N} \phi_{d,n}$$

## Updating $q(\beta_k|\lambda_k)$ posterior conditional in Exponential Family form:

$$p(\beta_k|Z,W) = p(\beta_k|\eta) \prod_{d=1}^{D} \prod_{n=1}^{N} p\left(w_{d,n}|\beta_k\right)^{\delta(z_{d,n},k)} = \text{Dir}(\eta) \times \prod_{d=1}^{D} \prod_{n=1}^{N} \beta_k^{w_{d,n}\delta(z_{d,n},k)}$$

$$\propto \exp\left(\underbrace{\left(\eta - 1 + \sum_{d=1}^{D} \sum_{n=1}^{N} w_{d,n}\delta(z_{d,n},k)\right)}_{\eta_l(\eta,Z,W)} \times \underbrace{\log(\beta_k)}_{t(\beta_k)}\right)$$

## Updating $q(\beta_k|\lambda_k)$ optimize $\lambda_k$

- In terms of natural parameter:

$$\begin{split} \eta(\lambda_k) &= \mathbb{E}_{\prod_{d=1}^D \prod_{m=1}^N q(z_{d,n})} \left[ \eta_1 \left( \eta, Z, W \right) \right] \\ &= \mathbb{E}_{\prod_{d=1}^D \prod_{m=1}^N q(z_{d,n})} \left[ \eta - 1 + \sum_{d=1}^D \sum_{n=1}^N w_{d,n} \delta(z_{d,n}, k) \right] \\ &= \eta - 1 + \sum_{d=1}^D \sum_{n=1}^N w_{d,n} \phi_{d,n}^k \end{split}$$

Change it back to traditional parameter:

$$\lambda_k = \eta + \sum_{d=1}^{D} \sum_{n=1}^{N} \mathbf{w}_{d,n} \phi_{d,n}^k$$

## Collapsed Variational Inference

$$q(z_{d,n}) = \mathsf{Mult}(\phi_{d,n}) \text{ or } q(z_{d,n} = k) = \phi_{d,n}^k \qquad q(\beta_k) = \mathsf{Dir}(\lambda_k) \qquad q(\theta_d) = \mathsf{Dir}(\gamma_d)$$

$$\implies q(Z,\theta_1\dots\theta_D,\beta_1\dots\beta_K) = \left(\prod_{d=1}^{d=D}\prod_{n=1}^N q(Z_{d,n}|\phi_{d,n})\right)\prod_{d=1}^D q(\theta_d|\gamma_d)\prod_{k=1}^K q(\theta_k|\lambda_k)$$
 now change to: 
$$= \underbrace{\left(\prod_{d=1}^{d=D}\prod_{n=1}^N q(Z_{d,n}|\phi_{d,n})\right)}_{q(Z)}q(\Theta,\beta|Z)$$

Maximize ELOB, it becomes: (remove X for clarity) Let  $U = \{\Theta, \beta\}$ :

$$\begin{split} \mathcal{L}(q) &\triangleq \mathbb{E}_{q(U,Z)}[\log p(Z,U)] - \mathbb{E}_{q(U,Z)}[\log q(Z,U)] \\ &= \mathbb{E}_{q(U,Z)}[\log p(Z,U)] - \mathbb{E}_{q(U,Z)}[\log q(U|Z) - \log q(Z)] \\ &= \mathbb{E}_{q(Z)} \left( \mathbb{E}_{q(U|Z)}[\log p(Z,U)] \right) - \mathbb{E}_{q(Z)} \left( \mathbb{E}_{q(U|Z)}[\log q(U|Z)] \right) - \mathbb{E}_{q(Z,U)}[\log q(Z)] \\ &= \mathbb{E}_{q(Z)} \left( \underbrace{\mathbb{E}_{q(U|Z)}[\log p(Z,U)] - [\log q(U|Z)]}_{\mathcal{L}(q(U|Z))} \right) - \mathbb{E}_{q(Z)}[\log q(Z)] \end{split}$$

Think this as treating Z as X.

## Collapsed Variational Inference (2)

(removed X for clarity)

$$\begin{split} \arg\max_{q(U|Z)}(\mathcal{L}(q)) &= \arg\max_{q(U|Z)} \left[ \mathbb{E}_{q(Z)} \left( \underbrace{\mathbb{E}_{q(U|Z)} \left( [\log p_X(Z,U)] - [\log q(U|Z)] \right)}_{\mathcal{L}(q(U|Z))} \right) - \mathbb{E}_{q(Z)} [\log q(Z)] \right] \\ &= \mathbb{E}_{q(Z)} \left( \arg\max_{q(U|Z)} \left[ \mathbb{E}_{q(U|Z)} \left( [\log p(Z,U)] - [\log q(U|Z)] \right) \right] \right) - \mathbb{E}_{q(Z)} [\log q(Z)] \\ &= \mathbb{E}_{q(Z)} [p(Z)] - \mathbb{E}_{q(Z)} [\log q(Z)] \\ &= \arg\max_{q(U|Z)} \left[ \mathbb{E}_{q(U|Z)} \left( [\log p(Z,U)] - [\log q(U|Z)] \right) \right] = p(Z) \end{split}$$

4 □ → 4 同 → 4 目 → 4 目 → 9 Q P

maximum occur when  $q(U|Z) = p(U|Z) \implies \mathbb{KL} (q(U|Z)||p(U|Z)) = 0$
